

Regular Languages 2 of 3

Deterministic Finite State Automata (DFSA)

Ex 1: of a DFSA

Example input: 110100

State	q_0	q_1	q_3	q_0	q_1	q_2	q_2
Input symbol		1	1	0	1	0	0

The string is rejected since q_2 is not an accepting state.

Accepting states: q_0, q_1

Not accepting states: q_2, q_3

Definition:

A DFSA M is a 5-tuple $M = (Q, \Sigma, \delta, s, F)$, where

- Q is a finite set of states
- Σ is the input alphabet
- δ is the transition function $\rightarrow \delta : Q \times \Sigma \rightarrow Q$
e.g. $\delta(q, c) = q'$
- $s \in Q$ is the initial state
- $F \subseteq Q$ is the set of accepting state.

Extended Transition Function

$$\delta^* : Q \times \Sigma^* \rightarrow Q$$

$\delta^*(q, x) = q'$ means if we start at q and read x (a string), then we end at q' .

$$\delta^*(q, x) = \begin{cases} q & \text{if } x = \epsilon \\ \delta(\delta^*(q, y), a) & \text{if } x = ya, \text{ where } y \in \Sigma^*, a \in \Sigma \end{cases}$$

Definition:

We say a DFSA $M = (Q, \Sigma, \delta, s, F)$ **accepts** a string $x \in \Sigma^*$ iff $\delta^*(s, x) \in F$ (M accepts F)

The language of a DFSA M is

$$\mathcal{L}(M) = \{ x \in \Sigma^* : M \text{ accepts } x \}$$

Ex 2: What is $L(M)$ from Ex 1?

$$L(M) = \{x \in \Sigma^* : x \text{ has an odd \# of 1s iff } x \text{ ends with 1}\}$$

How to prove Ex 2?

We use a state invariant

$$\delta^*(s, x) = \begin{cases} q_0, & \text{if } ______ \\ q_1, & \text{if } ______ \\ \vdots & \end{cases} \quad (SI)$$

Ex 3: Find SI of Ex 2

$$\delta^*(q_0, x) = \begin{cases} q_0, & \text{if has an even \# of 1s and } x \text{ doesn't end with 1} \\ q_1, & \text{if has an odd \# of 1s and } x \text{ ends with 1} \\ q_2, & \text{if has an odd \# of 1s and } x \text{ doesn't end with 1} \\ q_3, & \text{if has an even \# of 1s and } x \text{ ends with 1} \end{cases}$$

Conventions

Combining transitions

Omitting dead states

Non deterministic Finite State Automata (NFA)

A DFA with 2 features.

(i) Multiple choices when reading a symbol

(ii) Epsilon transitions. Change state without reading any input.

Ex 4: of a NFA

Input: 00

Trace 1: $q_0 \xrightarrow{0} q_1 \xrightarrow{0} q_2$ reject

Trace 2: $q_0 \xrightarrow{0} q_1 \xrightarrow{0} q_2 \xrightarrow{\epsilon} q_0$ accept

Trace 3: $q_0 \xrightarrow{0} q_2 \xrightarrow{0} q_0$ accept

Trace 4: $q_0 \xrightarrow{0} q_2 \xrightarrow{\epsilon} q_0 \xrightarrow{0} q_1$ reject

The traces are called computations.

Definition:

An NFSA M accepts an input x iff there's an accepting computation of M on x .
 iff $\delta^*(q_0, x) \cap F \neq \emptyset$

The language of an NFSA M is

$$\mathcal{L}(M) = \{ x \in \Sigma^* : M \text{ accepts } x \}$$

Ex 5: Find $\mathcal{L}(M)$ of Ex 4.

$$\mathcal{L}(M) = \mathcal{L}(((\epsilon + 0 + 1)0(0 + \epsilon))^*)$$

Definition:

An NFSA M is a 5-tuple $M = (Q, \Sigma, \delta, s, F)$, where

↳ Q, Σ, s, F are as in a DFSA.

↳ δ is the transition function.

$$\delta: Q \times (\Sigma \cup \{\epsilon\}) \rightarrow \mathcal{P}(Q)$$

e.g. in Ex 4, $\delta(q_0, 0) = \{q_1, q_2\}$

Extended Transition Function

$$\delta^*: Q \times \Sigma^* \rightarrow \mathcal{P}(Q)$$

$\delta^*(q, x)$ is the set of states that are readable starting at a state q and reading all of x .

Ex 6: δ^* of Ex 4.

$$\delta^*(q_0, 0) = \{q_0, q_1, q_2\}$$

$$\delta^*(q_0, 1) = \{q_1\}$$

$$\delta^*(q_0, 11) = \emptyset$$

Ex 7: Find an equivalent DFSA M' (Subset construction)

Simplified DFSA:

Theorem: The BIG Result

Let L be a language. Then the following are equivalent.

- (i) $L = \mathcal{L}(R)$ for some regex R
- (ii) $L = \mathcal{L}(M)$ for some DFSA M
- (iii) $L = \mathcal{L}(M)$ for some NFSA M
